1 Introduction

The Tor network currently consists of thousands of nodes which route anonymous internet traffic daily. The nonprofit organization *TorProject*¹ already provides an archive with raw historic data about the network. This raw data is difficult to analyze and grasp. With our app TorMap we want to visualize, group and filter public Tor relays on a world map. The state of the network can be viewed for any day between October 2007 and today. Getting details like IP address, contact or Autonomous System info of a relay is as easy as selecting it on the map.

2 Technical documentation

TorMap consists of a *ReactJS*² web app (frontend) and a JVM based web server (backend). The backend periodically fetches data from the *TorProject archive*³ and stores processed and enriched data in a local database. This data can then be fetched by the frontend with short response times.

2.1 Frontend

The frontend is written in *TypeScript*⁴ which is an open-source language that builds on top of JavaScript, and adds static type definitions. This helps catching errors and creating code that is easier to read and understand.

As base for data visualization, we used *Leaflet*⁵ which is a popular JavaScript library for interactive maps. The user interface is designed with *Material UI*⁶ which is a package for react that implements all the design principles of *Material Design*⁷. It allows designing a UI with minimal effort and great results.

The data for geo located relays is queried from the backend via a REST API. All further manipulations on this data set is done by the frontend before each rendering. Each time the selected date or settings get changed, will result in a new rendering. The pure time for rendering depends on the performance of the device but should be less than 60ms on an average computer. Therefore the limiting factor of the re-render time is the network bandwidth. The frontend is designed to work well on devices with a fast internet connection.

2.1.1 Packet structure

For dependency management and build generation *Yarn*⁸ is used. All source code is located in `frontend/src/`.

Point of Entry: The root of our app is `App.tsx` where the general state necessary for the app is managed and all further components are being called.

components: All components that make up the app are located in this folder.

data: Data that is directly included in the app and does not get loaded separately. E.g. GeoJSON for countries

types: All TypeScript definitions used in the app should be located here. Definitions that are used in one component only can also be declared in the components file directly.

util: All helpers, as well as the config-file are located here. Helpers are additional React-Hooks, and functions that got outsourced from their component or don't belong to a specific component.

2.2 Backend

The backend is written in *Kotlin*⁹ which is a modern approach to writing easy to maintain and save JVM based applications. Since 2019 Google also advises to use Kotlin as the main programming language for android apps [1]. We use the *Spring Boot Framework*¹⁰ as a standalone web server, which provides a REST API to be consumed by the frontend.

2.2.1 Packet structure

For dependency management and build generation *Gradle*¹¹ is used. All source code is located in `backend/src/main/kotlin/`. The `com.ip2location` package contains an *implementation by IP2Location*¹² to resolve IP addresses to a geographic location. The `org.tormap` package contains the main class `TorMapApplication.kt` which starts the backend server. The package also contains the rest of our backend application:

adapter: This package contains controllers which define the REST API endpoints.

config: This package contains config classes which model and document the user defined config in `src/main/resources/application.pr`. The classes attributes are mapped to the user config at runtime.

database: This package contains JPA database entities in `database/entity` which model the DB tables. In `database/repository` repositories can be used to execute abstract Hibernate queries on the JPA entities.

service: This package contains services like the *SchedulerService* or *IpLookupService*. They interact with other services and the DB repositories to process and persist data.

2.2.2 API specification

TorMap uses the *OpenAPI*¹³ standard for describing it's API and an interactive view of it called *Swagger*¹⁴. To use the interactive version start the backend and go to `http://localhost:8080/documentation` or for raw JSON output `http://localhost:8080/documentation/json`.

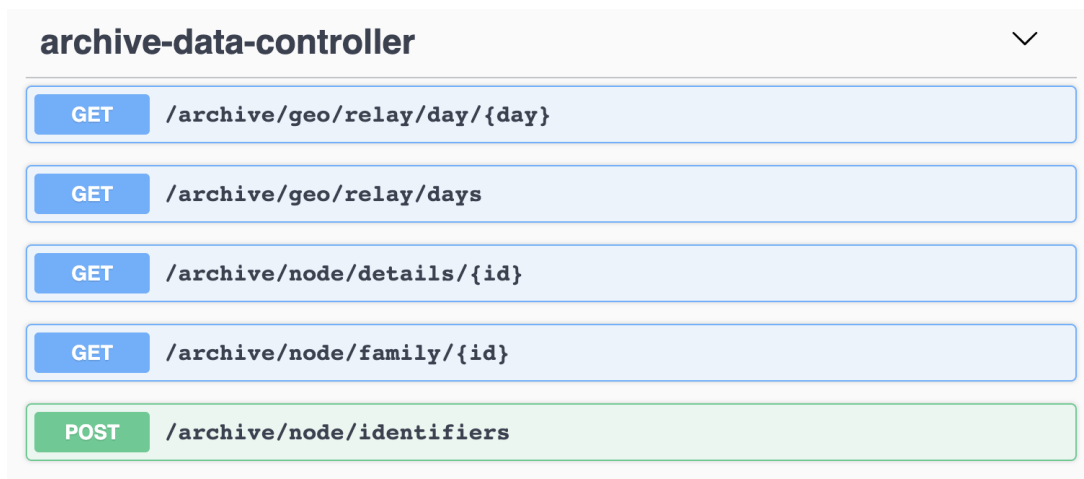

Figure 1: The API provides endpoints for: fetching geo relays for a single day, fetching available geo relay days, fetching details of a single node, fetching the details about a family, fetching node identifiers like nickname and fingerprint for a list of given ids.

2.2.3 Database and model

TorMap uses an embedded H2 database, which is saved locally in a single file. This enables us to deploy the backend with an preprocessed DB file, since the process of downloading and enriching all necessary data from the TorProject archive takes a lot of time. The main point of discussion was at what precision processed descriptors should be saved (hour / day / month / year). Since raw descriptor data used for TorMap is quite large (currently aprox. 33GB) and will become ever growing in the future, we decided to keep day precision for geo relays and month precision for details about nodes.

To manage future DB model migrations new SQL changelogs can be added under `src/main/resources/db/migration`. Our DB migration tool *Flyway*¹⁵ then checks if new changelogs need to be executed on backend startup. The DB model is represented in Spring with *JPA entities*¹⁶, which will be validated against the DB on backend startup. We use *Hibernate*¹⁷ to construct simple queries against the DB.

📊 NODE_DETAILS

📍 ID	bigint
📄 ADDRESS	varchar(15)
🔌 ALLOW_SINGLE_HOP_EXITS	boolean
📄 AUTONOMOUS_SYSTEM_NAME	varchar(255)
📄 AUTONOMOUS_SYSTEM_NUMBER	varchar(10)
📈 BANDWIDTH_BURST	integer
📈 BANDWIDTH_OBSERVED	integer
📈 BANDWIDTH_RATE	integer
📄 CACHES_EXTRA_INFO	boolean
📄 CIRCUIT_PROTOCOL_VERSIONS	varchar(255)
📄 CONTACT	varchar(255)
📅 DAY	date
📄 FAMILY_ENTRIES	clob
📄 FAMILY_ID	bigint
📄 FINGERPRINT	varchar(40)
🔌 IS_HIBERNATING	boolean
🔌 IS_HIDDEN_SERVICE_DIR	boolean
📄 LINK_PROTOCOL_VERSIONS	varchar(255)
📄 MONTH	varchar(255)
📄 NICKNAME	varchar(19)
📄 PLATFORM	varchar(255)
📄 PROTOCOLS	varchar(255)
🔌 TUNNELLED_DIR_SERVER	boolean
📅 UPTIME	bigint

📊 GEO_RELAY

📍 ID	bigint
📄 COUNTRY_CODE	varchar(2)
📅 DAY	date
📄 FINGERPRINT	varchar(40)
📄 FLAGS	varchar(255)
📄 LATITUDE	decimal(6,4)
📄 LONGITUDE	decimal(7,4)

📊 DESCRIPTORS_FILE

📍 FILENAME	varchar(255)
📄 TYPE	integer
📅 LAST_MODIFIED	bigint
📅 PROCESSED_AT	timestamp

📊 flyway_schema_history

📍 installed_rank	int
📄 version	varchar(50)
📄 description	varchar(200)
📄 type	varchar(20)
📄 script	varchar(1000)
📄 checksum	int
📄 installed_by	varchar(100)
📅 installed_on	timestamp
📅 execution_time	int
🔌 success	boolean

📊 AUTONOMOUS_SYSTEM

📍 IP_FROM	bigint
📍 IP_TO	bigint
📄 CIDR	varchar(43)
📄 AUTONOMOUS_SYSTEM_NUMBER	varchar(10)
📄 AUTONOMOUS_SYSTEM_NAME	varchar(255)

Figure 2: **NODE_DETAILS** - stores a processed version of relay server *descriptors* with monthly precision.
GEO_RELAY - stores geographic locations of relays contained in *consensus descriptors* with day precision.
DESCRIPTORS_FILE - stores which descriptor files have been processed already.
AUTONOMOUS_SYSTEM - stores data imported from an IP2Location CSV file.
flyway_schema_history - used by the Flyway DB migration tool, which checks if migrations need to be applied.

3 Server setup

4 Development setup

4.0.1 Frontend

4.0.2 Backend

5 Usage manual

TorMap is a web app that can be used in all modern web-browsers where JavaScript is enabled. The app is mainly optimized for usage on devices with a larger screen and good connectivity.

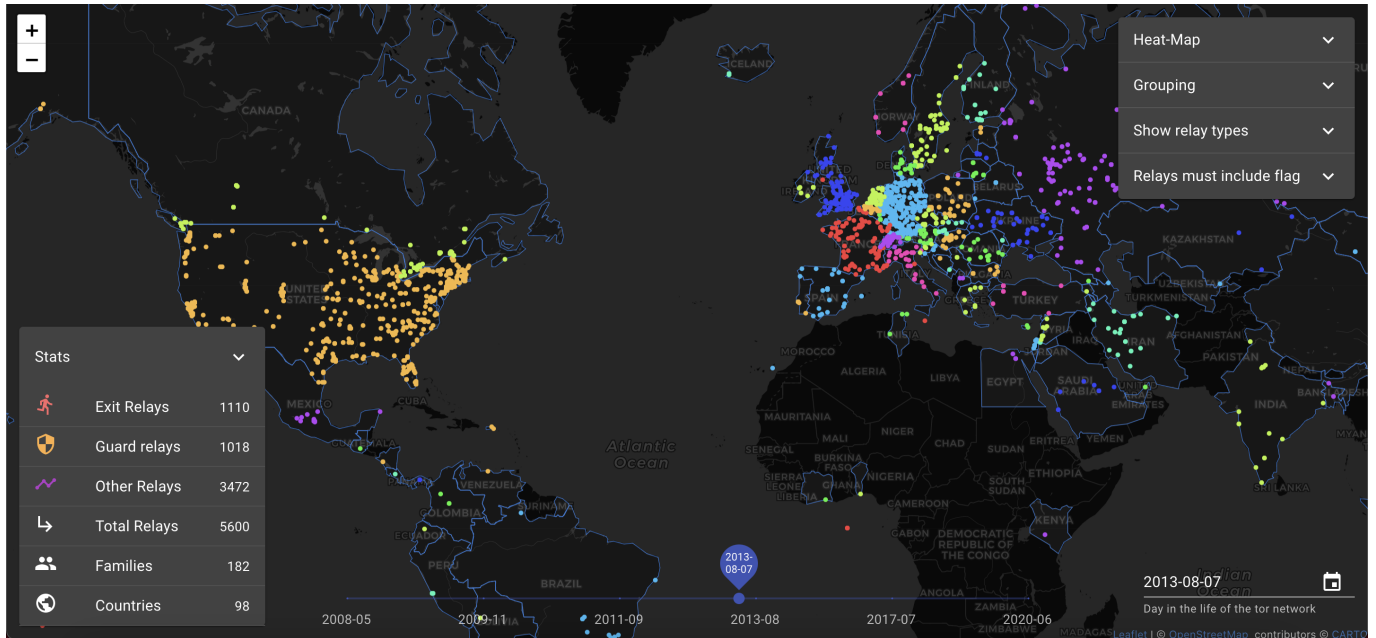

Figure 3: A screenshot of the frontend UI

5.1 Date selection

The TorMap app visualizes historic data between October 2007 and yesterday and let's the user select any day of interest. By default the latest available day is selected. To change the selected day, there are these options:

- Slider - you can select an date on the slider by moving it.
- Arrow-Keys - if the slider was just in use, you are able to move the slider with arrow-keys for small steps.
- Date picker - the date picker offers two options:
 - Text input - entering a date with number keys
 - Date picker - by clicking on the calendar icon

5.2 Change settings

The settings are located in the top right corner, in form of an accordion-menu. This menu has four parts.

5.2.1 Heat-map

A Heat-map is an overlay over that will be rendered on top of other marker levels.

- Visualize the density of relays

5.2.2 Grouping relays

- Group by family - will add coloured markers for each family of relays. The size of markers indicates the amount of family members at a specific coordinate. If there is only one family at a given coordinate it can be selected by mouse-click. Should there be multiple different families at a coordinate, a dialog opens where a family can be selected.

-
- Group by country - will add borders highlighting available countries which are selectable. Additionally all relays of the same country will be rendered in the same color.
 - Group by coordinates - if there are more than 4 relays at the same point, a circle is added indicating the amount of relays at this location.

5.2.3 Relay types

The types option allows to exclude relays of a specific type from rendering. The type of a relay is:

- Exit relay - if the relay has the 'exit'-flag
- Guard relay - if the relay has the 'guard'-flag and not the 'exit'-flag
- Default relay - if the relay has neither the 'exit'- or 'guard'-flag

5.2.4 Relay flags

The flags filter allows the user to only view relays that have a specific set of flags.

5.3 Statistics

The statistics are located in the lower left corner, in form of an accordion-menu. For the calculation of the statistics only those relays get counted which match the current selection. Therefore if Germany is selected, only relays who's IP address belongs to Germany (according to the used IP to geolocation service) will be counted. If a family (relays that belong to the same organisation/owner) is selected, only the family members are counted. As families can span across multiple countries, if a family and a country are selected only the family members in the selected country are counted. If no family or country is selected, the amount of different selectable families and countries is displayed.

6 Feature list

This section lists all available features for the end user:

- Date selection
 - via slider
 - via text input
 - via date picker
- Filter relays
 - by type
 - by flags
- Group Relays
 - by family
 - by country
 - by coordinates
- Show statistics for selected day
 - Amount of relays for each relay type
 - Total amount of relays
 - Total amount of different families
 - Total amount of different countries where at least one relay is hosted
- Show a map with markers for selected day and selected settings
 - Markers for relays
 - Markers for families (if selected in settings)

- Country borders (if grouping by countries is selected in settings)
- Markers for multiple relays on the same coordinate (if selected in settings)
- A heat-map for the density of markers
- Show details dialog for any relay on the map

7 Conclusion and outlook

The TorMap app visualizes the ever growing Tor network in form of an interactive world map with a bunch of different visualizations. But the backend server also provides an open REST API to query geo data and node details of relays recorded between October 2007 and yesterday.

Nevertheless we see a bunch of potential for further implementations in form of new endpoints for the REST API of the backend as well as more visualizations and filters in the frontend that would illustrate the fast transformations happening in the structure of the Tor network.

7.1 Range slider

At the moment it is only possible to query the Data for an specific day in the life of the Tor network. The option to compare two different days would give a lot of further insights in to the changes happening in the network.

7.2 Bandwidth

Tor relays keep track of how much bandwidth they have spend on incoming and outgoing traffic. Visualization on the bandwidth of nodes could give insight to the flow of the network traffic of the Tor network.

7.3 Major events

Additional marks on the slider, marking major international and political events that had a 'higher' impact on the Tor network. For example 2009-09-24 to 2009-09-25 when over night 100+ relays disappeared in China.

7.4 Comparison to country metadata

For now the frontend includes an *GeoJSON*¹⁸ file which contains data about countries. This is used to draw the country boarders on the map. The file also includes meta data about country's, e.g. their population. If this data can be queried for selected days, it's possible to create views that compare the Tor network activity to properties of a country.

7.5 Auto moving slider

A function to let the slider move automatically trough history to visualize changes of size and distribution of the Tor network.
